Overview

- ◆ Background
- ◆ Pocket Switched Networking
- ◆ Challenges in PSN
- ◆ Huggle: our implementation of PSN

intel

2

WAC 2005

Mobile wireless devices present a new environment

- ◆ Mobile device capabilities
 - ✦ Computing power: exponential growth
 - ✦ Storage: likewise
 - ✦ Programmability; general purpose apps
 - ✦ Multiple wireless network interfaces
 - ✦ Human-driven mobility

Problem Statement

- ◆ Mobility pattern influences networking
 - ✦ Constantly changing set of “local” devices
 - ✦ Occasional “global” (i.e. Internet) connectivity, depending on location and willingness to pay
 - ✦ Data can be physically carried from a to b.
- ◆ IP-centric networking has bad assumptions
 - ✦ Contemporaneous connectivity between hosts
 - ✦ Can perform address resolution before data tx
 - ✦ Role of network confined to delivery

Current result: User inconvenience when connectivity is dynamic

- ◆ Many different applications with same user-level purpose
 - ⊕ Messaging: Email vs. IM vs. web chat
 - ⊕ Photo sharing: Bluetooth vs. USB key vs. website upload
- ◆ Users have to understand which app to use and when
- ◆ Many applications are only useful when connected in specific ways

Pocket Switched Networking: Aims

- ◆ Replace socks/TCP/IP as the API for networking on mobile devices
- ◆ Data should be delivered using *local connectivity*, *global connectivity*, and *user mobility* transparently
- ◆ Discard end-to-end: intermediate nodes are powerful, may be interested in the data, and can help with routing

Pocket Switched Networking: Principles

- ◆ Use messages rather than packets so that intermediate nodes can participate fully
- ◆ Expose as much meta-data to the network layer as possible to allow content-based forwarding
 - ✦ E.g. send to “Jon”, or “anyone with latest football score”
- ◆ Routing decisions made locally based on knowledge of dynamic environment
- ◆ PSN is the filesystem as well as the network; all data is “public” to some extent
 - ✦ E.g. share webpages with anyone, share private files between a user’s devices

WAC 2005

Pocket Switched Networking: Challenges

- ◆ Distributed naming/addressing
 - ✦ Cannot do many-round-trip lookups c.f. Internet
- ◆ Forwarding without flooding
 - ✦ Need to learn network state and target messages
- ◆ Security, trust, incentives/policing
 - ✦ Without access to infrastructure services
- ◆ Usability and privacy
 - ✦ How do we portray to user?
- ◆ Resource management
 - ✦ Don’t kill my battery to service stranger’s requests

intel

8

WAC 2005

Naming/Addressing

- ◆ Use names representing user-level entities such as people, places, and info
 - ✦ “Jon”, “Intel Research Cambridge”, “current news”
- ◆ Names potentially map onto many nodes
 - ✦ E.g. My notebook *or* my mobile phone
 - ✦ E.g. Any device in Intel Research Cambridge
- ◆ Addresses annotate names with forwarding hints
 - ✦ e.g. “James” maps to: “Intel” community; seen today in Greece; email address james.w.scott@intel.com, phone number +447970123456

Forwarding

- ◆ Node mobility means each message may take different route
- ◆ Need to learn about and internally model the network behaviour
- ◆ Make use of addressing hints as well as dynamic state information learnt from neighbours
 - ✦ e.g. Device X saw James’s laptop 1 hour ago
- ◆ Potentially use multiple, diverse paths
- ◆ Support both push and pull...

Push and Pull Illustrated

Node A

Type: webpage
Keywords: news
Date: 09:30 11/9/01

PUSH
To: B
From: A

Node B

PULL
From: B
Keywords: "news"
Date: >09:00 11/9/01

11

Push and Pull Illustrated

Node A

Type: webpage
Keywords: news
Date: 09:30 11/9/01

PUSH
To: B
From: A

Node B

PULL
From: B
Keywords: "news"
Date: >09:00 11/9/01

12

Security, Trust and Incentives

- ◆ Need to encrypt data appropriately for the security domains encountered
 - ✦ Secrets can go from my mobile phone to my laptop via your phone, if encrypted appropriately
- ◆ Distributed trust management required
 - ✦ Prerequisite for encryption/authentication
 - ✦ Local communications means no certificate authorities
- ◆ Reputation systems may be used to provide incentives to play nice
 - ✦ “familiar strangers” [Paulos]
 - ✦ c.f. resource management later

Usability and Privacy

- ◆ Usability will require informing the user about network state issues – but how?
 - ✦ Spinning globe, signal strength bars, greyed-out names in IM
- ◆ Privacy is compromised in new ways
 - ✦ Sharing meta-data with neighbouring nodes means disclosing information
 - ✦ Must provide a way for users to mentally model and control the privacy/functionality tradeoff

Resource Management

- ◆ Storage, CPU not a problem
 - ✦ Moore's law growth
 - ✦ Prioritisation is fairly simple
- ◆ Network and battery life more constrained
 - ✦ Use automatic policy as well as manual control
 - ✦ Nodes are often connected to power or Internet, and may also *predict* connectivity

Haggle: our PSN implementation

- ◆ Preliminary ideas – work starts Jan 2006 under EU FET Autonomic Communications project
- ◆ Build a reference PSN implementation
 - ✦ Cross platform
 - ✦ Cross network technology
 - ✦ Integration with legacy systems (e.g. email, web)
 - ✦ Modular, especially for forwarding and security

Haggle Architecture

↓ Data
↓ Control

17

WAC 2005

Haggle Applications

- ◆ Asynchronous messaging
 - ✦ Subsumes email, IM, SMS
- ◆ Usenet-style newsgroups
 - ✦ Existing app which handles disconnection well
- ◆ Querying in the local environment
 - ✦ ["world news", age < 1 hour]
 - ✦ Automatic caching
- ◆ File sharing
 - ✦ Photos/documents (e.g. this ppt file)
- ◆ Data synchronisation
 - ✦ support user's "cloud" of devices
