

## Time Series Databases

- A time series is a sequence of real numbers, representing the measurements of a real variable at equal time intervals
  - Stock price movements
  - Volume of sales over time
  - Daily temperature readings
  - ECG data
- A time series database is a large collection of time series

10/27/2006 Time Series Similarity Measures  
– all NYSE stocks

1

## Classical Time Series Analysis

(not the focus of this tutorial)

- Identifying Patterns
  - Trend analysis
    - A company's linear growth in sales over the years
  - Seasonality
    - Winter sales are approximately twice summer sales
- Forecasting
  - What is the expected sales for the next quarter?

10/27/2006 Time Series Similarity Measures

2

# Time Series Problems

(from a databases perspective)

- The Similarity Problem

$$X = x_1, x_2, \dots, x_n$$

$$Y = y_1, y_2, \dots, y_n$$

Define and compute  $\text{Sim}(X, Y)$

E.g. do stocks X and Y have similar movements?

10/27/2006

Time Series Similarity Measures

3

- Similarity measure should allow for imprecise matches
- Similarity algorithm should be very efficient
- It should be possible to use the similarity algorithm efficiently in other computations, such as
  - Indexing
  - Subsequence similarity
  - clustering
  - rule discovery
  - etc....

10/27/2006

Time Series Similarity Measures

4

- Indexing problem
  - Find all lakes whose water level fluctuations are similar to X
- Subsequence Similarity Problem
  - Find out other days in which stock X had similar movements as today
- Clustering problem
  - Group regions that have similar sales patterns
- Rule Discovery problem
  - Find rules such as “if stock X goes up and Y remains the same, then Z will shortly go down”

10/27/2006

Time Series Similarity Measures

5

## Examples

- Find companies with similar stock prices over a time interval
- Find products with similar sell cycles
- Cluster users with similar credit card utilization
- Cluster products
- Use patterns to classify a given time series
- Find patterns that are frequently repeated
- Find similar subsequences in DNA sequences
- Find scenes in video streams

10/27/2006

Time Series Similarity Measures

6

- Basic approach to the Indexing problem

Extract a few key “features” for each time series  
Map each time sequence  $X$  to a point  $f(X)$  in the (relatively low dimensional) “feature space”, such that the (dis) similarity between  $X$  and  $Y$  is approximately equal to the Euclidean distance between the two points  $f(X)$  and  $f(Y)$

Use any well-known spatial access method (SAM) for indexing the feature space

10/27/2006

Time Series Similarity Measures

7

- Scalability an important issue
  - If similarity measures, time series models, etc. become more sophisticated, then the other problems (indexing, clustering, etc.) become prohibitive to solve
- Research challenge
  - Design solutions that attempt to strike a balance between accuracy and efficiency

10/27/2006

Time Series Similarity Measures

8

## Outline of Tutorial

- Part I
  - Discussion of various similarity measures
- Part II
  - Discussion of various solutions to the other problems, such as indexing, subsequence similarity, etc
  - Query language support for time series
  - Miscellaneous issues ...

10/27/2006

Time Series Similarity Measures

9

## Euclidean Similarity Measure

- View each sequence as a point in n-dimensional Euclidean space ( $n = \text{length of sequence}$ )
- Define (dis)similarity between sequences X and Y as

$$L_p(X, Y)$$

10/27/2006

Time Series Similarity Measures

10

## Advantages

- Easy to compute
- Allows scalable solutions to the other problems, such as
  - indexing
  - clustering
  - etc...

10/27/2006

Time Series Similarity Measures

11

## Disadvantages

- Does not allow for different baselines
  - Stock X fluctuates at \$100, stock Y at \$30
- Does not allow for different scales
  - Stock X fluctuates between \$95 and \$105, stock Y between \$20 and \$40

10/27/2006

Time Series Similarity Measures

12

## Normalization of Sequences

[Goldin and Kanellakis, 1995]

- Normalize the mean and variance for each sequence

Let  $\mu(X)$  and  $\rho(X)$  be the mean and variance of sequence  $X$

Replace sequence  $X$  by sequence  $X'$ , where

$$X'_i = (X_i - \mu(X)) / \rho(X)$$

10/27/2006

Time Series Similarity Measures

13

## Similarity definition still too rigid

- Does not allow for noise or short-term fluctuations
- Does not allow for phase shifts in time
- Does not allow for acceleration-deceleration along the time dimension
- etc ....

10/27/2006

Time Series Similarity Measures

14

## Example

10/27/2006

Time Series Similarity Measures

15

## A general similarity framework involving a transformation rules language

[Jagadish, Mendelzon, Milo]

Each rule has an associated cost

10/27/2006

Time Series Similarity Measures

16

## Examples of Transformation Rules

- Collapse adjacent segments into one segment

new slope = weighted average of previous slopes

new length = sum of previous lengths

10/27/2006

Time Series Similarity Measures

17

## Combinations of Moving Averages, Scales, and Shifts

[Rafiei and Mendelzon, 1998]

– Moving averages are a well-known technique for  
smoothing time sequences

- Example of a 3-day moving average

$$x'_i = (x_{i-1} + x_i + x_{i+1})/3$$

10/27/2006

Time Series Similarity Measures

18

## Disadvantages of Transformation Rules

- Subsequent computations (such as the indexing problem) become more complicated
  - Feature extraction becomes difficult, especially if the rules to apply become dependent on the particular X and Y in question
  - Euclidean distances in the feature space may not be good approximations of the sequence distances in the original space

10/27/2006

Time Series Similarity Measures

19

## Dynamic Time Warping

[Berndt, Clifford, 1994]

- Extensively used in speech recognition
- Allows acceleration-deceleration of signals along the time dimension
- Basic idea
  - Consider  $X = x_1, x_2, \dots, x_n$ , and  $Y = y_1, y_2, \dots, y_n$
  - We are allowed to extend each sequence by repeating elements
  - Euclidean distance now calculated between the extended sequences  $X'$  and  $Y'$

10/27/2006

Time Series Similarity Measures

20

## Dynamic Time Warping

[Berndt, Clifford, 1994]

10/27/2006

Time Series Similarity Measures

21

## Restrictions on Warping Paths

- Monotonicity
  - Path should not go down or to the left
- Continuity
  - No elements may be skipped in a sequence
- Warping Window
  - $|i - j| \leq w$
- Others .....

10/27/2006

Time Series Similarity Measures

22

## Formulation

- Let  $D(i, j)$  refer to the dynamic time warping distance between the subsequences

$x_1, x_2, \dots, x_i$

$y_1, y_2, \dots, y_j$

$$D(i, j) = |x_i - y_j| + \min \{ D(i-1, j), \\ D(i-1, j-1), \\ D(i, j-1) \}$$

10/27/2006

Time Series Similarity Measures

23

## Solution by Dynamic Programming

- Basic implementation =  $O(n^2)$  where  $n$  is the length of the sequences
  - will have to solve the problem for each  $(i, j)$  pair
- If warping window is specified, then  $O(nw)$ 
  - Only solve for the  $(i, j)$  pairs where  $|i - j| \leq w$

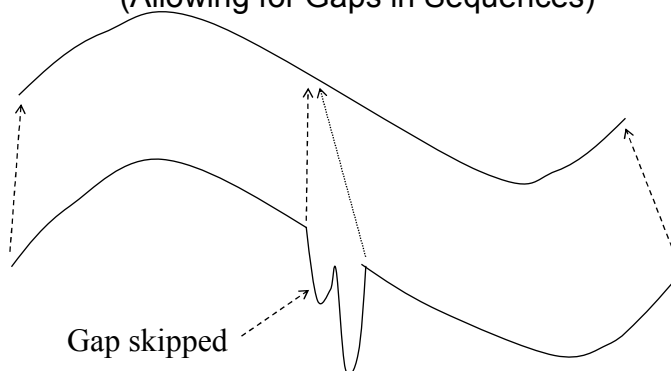

10/27/2006

Time Series Similarity Measures

24

## Longest Common Subsequence Measures

(Allowing for Gaps in Sequences)

10/27/2006

Time Series Similarity Measures

25

### Basic LCS Idea

X = 3, 2, 5, 7, 4, 8, 10, 7

Y = 2, 5, 4, 7, 3, 10, 8, 6

LCS = 2, 5, 7, 10

$$\text{Sim}(X, Y) = |\text{LCS}|$$

#### Shortcomings

Different scaling factors and baselines (thus need to scale, or transform one sequence to the other)

Should allow tolerance when comparing elements (even after transformation)

10/27/2006

Time Series Similarity Measures

26

- Longest Common Subsequences
  - Often used in other domains
    - Speech Recognition
    - Text Pattern Matching
  - Different flavors of the LCS concept
    - Edit Distance

10/27/2006

Time Series Similarity Measures

27

## LCS-like measures for time series

- Subsequence comparison without scaling [Yazdani & Ozsoyoglu, 1996]
- Subsequence comparison with local scaling and baselines [Agrawal et. al., 1995 ]
- Subsequence comparison with global scaling and baselines [Das et. al., 1997]
- Global scaling and shifting [Chu and Wong, 1999]

10/27/2006

Time Series Similarity Measures

28

## LCS without Scaling

[Yazdani & Ozsoyoglu, 1996]

Let  $\text{Sim}(i, j)$  refer to the similarity between the sequences  $x_1, x_2, \dots, x_i$  and  $y_1, y_2, \dots, y_j$

Let  $d$  be an allowed tolerance, called the “threshold distance”

If  $|x_i - y_j| < d$  then

$$\text{Sim}(i, j) = 1 + D(i - 1, j - 1)$$

else  $\text{Sim}(i, j) = \max\{D(i - 1, j), D(i, j - 1)\}$

10/27/2006

Time Series Similarity Measures

29

## LCS-like Similarity with Local Scaling

[Agrawal et al, 1995]

- Basic Ideas
  - Two sequences are similar if they have enough non-overlapping time-ordered pairs of subsequences that are similar
  - A pair of subsequences are similar if one can be scaled and translated appropriately to approximately resemble the other

10/27/2006

Time Series Similarity Measures

30

Three pairs of subsequences

Scale & translation different for each pair

10/27/2006

Time Series Similarity Measures

31

## The Algorithm

- Find all pairs of atomic subsequences in X and Y that are similar
  - atomic implies of a certain minimum size (say, a parameter  $w$ )
- Stitch similar windows to form pairs of larger similar subsequences
- Find a non-overlapping ordering of subsequence matches having the longest match length

10/27/2006

Time Series Similarity Measures

32

## LCS-like Similarity with Global Scaling

[Das, Gunopulos and Mannila, 1997]

- Basic idea: Two sequences  $X$  and  $Y$  are similar if they have long common subsequence  $X'$  and  $Y'$  such that

$$Y' \text{ is approximately } = aX' + b$$

- The scale+translation linear function is derived from the subsequences, and not from the original sequences
  - Thus outliers cannot taint the scale+translation function
- Algorithm
  - Linear-time randomized approximation algorithm

10/27/2006

Time Series Similarity Measures

33

- Main task for computing Sim
  - Locate a finite set of all *fundamentally different* linear functions
  - Run a dynamic-programming algorithm using each linear function
- Of the total possible linear functions, a constant fraction of them are *almost as good* as the optimal function
- The algorithm just picks a few (constant) number of functions at random and tries them out

10/27/2006

Time Series Similarity Measures

34

## Piecewise Linear Representation of Time Series

Time series approximated by K linear segments

10/27/2006

Time Series Similarity Measures

35

- Such approximation schemes
  - achieve data compression
  - allow scaling along the time axis
- How to select K?
  - Too small => many features lost
  - Too large => redundant information retained
- Given K, how to select the best-fitting segments?
  - Minimize some error function
- These problems pioneered in [Pavlidis & Horowitz 1974], further studied by [Keogh, 1997]

10/27/2006

Time Series Similarity Measures

36

## Defining Similarity

Distance = (weighted) sum of the difference of projected segments [Keogh & Pazzani, 1998]

10/27/2006

Time Series Similarity Measures

37

## Probabilistic Approaches to Similarity

[Keogh & Smyth, 1997]

- Probabilistic distance model between time series Q and R
  - Ideal template Q which can be “deformed” (according to a prior distribution) to generate the the observed data R
  - If D is the observed deformation between Q and R, we need to define the generative model  $p(D | Q)$

10/27/2006

Time Series Similarity Measures

38

- Piecewise linear representation of time series R
- Query Q represented as
  - a sequence of local features (e.g. peaks, troughs, plateaus ) which can be deformed according to prior distributions
  - global shape information represented as another prior on the relative location of the local features

## Properties of the Probabilistic Measure

- Handles scaling and offset translations
- Incorporation of prior knowledge into similarity measure
- Handles noise and uncertainty

## Probabilistic Generative Modeling Method

[Ge & Smyth, 2000]

- Previous methods primarily “distance based”, this method “model based”
- Basic ideas
  - Given sequence  $Q$ , construct a model  $M_Q$  (i.e. a probability distribution on waveforms)
  - Given a new pattern  $Q'$ , measure similarity by computing  $p(Q'|M_Q)$

10/27/2006

Time Series Similarity Measures

41

- The model  $M_Q$ 
  - a discrete-time finite-state Markov model
  - each segment in data corresponds to a state
    - data in each state typically generated by a regression curve
  - a state to state transition matrix is provided

10/27/2006

Time Series Similarity Measures

42

- On entering state  $i$ , a duration  $t$  is drawn from a state-duration distribution  $p(t)$ 
  - the process remains in state  $i$  for time  $t$
  - after this, the process transits to another state according to the state transition matrix

10/27/2006

Time Series Similarity Measures

43

## Example: output of Markov Model

Solid lines: the two states of the model

Dashed lines: the actual noisy observations

10/27/2006

Time Series Similarity Measures

44

## Relevance Feedback

[Keogh & Pazzani, 1999]

- Incorporates a user's subjective notion of similarity
- This similarity notion can be continually learned through user interaction
- Basic idea: Learn a user profile on what is different
  - Use the piece-wise linear partitioning time series representation technique
  - Define a Merge operation on time series representations
  - Use relevance feedback to refine the query shape

10/27/2006

Time Series Similarity Measures

45

## Landmarks

[Perng et. al., 2000]

- Similarity definition much closer to human perception (unlike Euclidean distance)
- A point on the curve is a  $n$ -th order landmark if the  $n$ -th derivative is 0
  - Thus, local max and mins are first order landmarks
- Landmark distances are tuples (e.g. in time and amplitude) that satisfy the triangle inequality
- Several transformations are defined, such as shifting, amplitude scaling, time warping, etc

10/27/2006

Time Series Similarity Measures

46

## Retrieval techniques for time-series

- **The Time series retrieval problem:**
  - Given a set of time series  $S$ , and a query time series  $S$ ,
  - find the series that are more similar to  $S$ .
- Applications:
  - Time series clustering for:  
financial, voice, marketing, medicine, video
  - Identifying trends
  - Nearest neighbor classification

10/27/2006

Time Series Similarity Measures

47

## The setting

- Sequence matching or subsequence matching
- Distance metric
- Nearest neighbor queries,  
range queries,  
all-pairs nearest neighbor queries

10/27/2006

Time Series Similarity Measures

48

## Retrieval algorithms

- We mainly consider the following setting:
  - the similarity function obeys the triangle inequality:  $D(A,B) < D(A,C) + D(C,B)$ .
  - the query is a full length time series
  - we solve the nearest neighbor query
- We briefly examine the other problems: no distance metric, subsequence matching, all-pairs nearest neighbors

10/27/2006

Time Series Similarity Measures

49

## Indexing sequences when the triangle inequality holds

- Typical distance metric:  $L_p$  norm.
- We use  $L_2$  as an example throughout:
  - $D(S,T) = (\sum_{i=1,\dots,n} (S[i] - T[i])^2)^{1/2}$

10/27/2006

Time Series Similarity Measures

50

## Dimensionality reduction

- The main idea: reduce the dimensionality of the space.
- Project the  $n$ -dimensional tuples that represent the time series in a  $k$ -dimensional space so that:
  - $k \ll n$
  - distances are preserved as well as possible

10/27/2006

Time Series Similarity Measures

51

## Dimensionality Reduction

- Use an indexing technique on the new space.
- GEMINI ([Faloutsos et al]):
  - Map the query  $S$  to the new space
  - Find nearest neighbors to  $S$  in the new space
  - Compute the actual distances and keep the closest

10/27/2006

Time Series Similarity Measures

52

## Dimensionality Reduction

- To guarantee no false dismissals we must be able to prove that:
  - $D(F(S), F(T)) < a D(S, T)$
  - for some constant  $a$
- a small rate of false positives is desirable, but not essential

10/27/2006

Time Series Similarity Measures

53

## What we achieve

- Indexing structures work much better in lower dimensionality spaces
- The distance computations run faster
- The size of the dataset is reduced, improving performance.

10/27/2006

Time Series Similarity Measures

54

## Dimensionality Techniques

- We will review a number of dimensionality techniques that can be applied in this context
  - SVD decomposition,
  - Discrete Fourier transform, and Discrete Cosine transform
  - Wavelets
  - Partitioning in the time domain
  - Random Projections
  - Multidimensional scaling
  - FastMap and its variants

10/27/2006

Time Series Similarity Measures

55

## The subsequence matching problem

- There is less work on this area
- The problem is more general and difficult
- [Faloutsos et al, 1994] [Park et al, 2000] [Kahveci, Singh, 2001] [Moon, Whang, Loh, 2001]
- Most of the previous dimensionality reduction techniques cannot be extended to handle the subsequence matching problem

10/27/2006

Time Series Similarity Measures

56

## The subsequence matching problem

- If the length of the subsequence is known, two general techniques can be applied:
  - Index all possible subsequences of given length  $k$ 
    - $n-w+1$  subsequences of length  $w$  for each time series of length  $n$
  - Partition each time series into fewer subsequences, and use an approximate matching retrieval mechanism

10/27/2006

Time Series Similarity Measures

57

## Similar sequence retrieval when triangle inequality doesn't hold

- In this case indexing techniques do not work (except for sequential scan)
- Most techniques try to speed up the sequential scan by bounding the distance from below.

10/27/2006

Time Series Similarity Measures

58

## Distance bounding techniques

- Use a dimensionality reduction technique that needs only distances (FastMap, MetricMap, MS)
- Use a pessimistic estimate to bound the actual distance (and possibly accept a number of false dismissals) [Kim, Park, and Chu, 2001]
- Index the time series dataset using the reduced dimensionality space

10/27/2006

Time Series Similarity Measures

59

## Example: Time warping and FastMap

[Yi et al, 1998]

- Given M time series
  - Find the  $M(M-1)/2$  distances using the time warping distance measure (does not satisfy the triangle inequality)
  - Use FastMap to project the time series to a k-dim space
- Given a query time series S,
  - Find the closest time series in the FastMap space
  - Retrieve them, and find the actual closest among them
- A heuristic technique: There is no guarantee that false dismissals are avoided

10/27/2006

Time Series Similarity Measures

60

## Indexing sequences of images

- When indexing sequences of images, similar ideas apply:
  - If the similarity/distance criterion is a metric,  
Use a dimensionality reduction technique
- [Yadzani and Ozsoyoglu]:
  - Map each image to a set of N features
  - Use a Longest Common Subsequence distance metric to find the distance between feature sequences
  - $\text{sim}(\text{ImageA}, \text{ImageB}) = \sum_{i=1..N} \text{sim}(FA_i - FB_i)$
- [Lee et al, 2000]:
  - Time warping distance measure
  - Use of Minimum Bounding Rectangles to lower bound the distance

10/27/2006

Time Series Similarity Measures

61

## Open problems

- Indexing non-metric distance functions
- Similarity models and indexing techniques for higher-dimensional time series
- Efficient trend detection/subsequence matching algorithms

10/27/2006

Time Series Similarity Measures

62

## Summary

- There is a lot of work in the database community on time series similarity measures and indexing techniques
- Motivation comes mainly from the clustering/unsupervised learning problem
- We look at simple similarity models that allow efficient indexing, and at more realistic similarity models where the indexing problem is not fully solved yet.
